Although Distribution boxes are properly set during installation, after a few years of winter freezing and summer thawing of the soil, they can move or settle from one side or the other.

Such tilting causes the septic effluent to unevenly flow toward some lateral openings, while others receive little or no wastewater. The result is that one section of a disposal bed may become more saturated than the rest or some trenches may become over-saturated, while others may dry out.

**New Jersey Septic Management Group** offers an easy and economical way to equalize wastewater distribution, through the installation of multiple **SPEED-LEVELERS**. One Speed-leveler is snapped into the mouth of each of the lateral pipes (exposed inside the d-box) and they are then rotated to the desired position, by hand. The Flo-Hole can be positioned to allow effluent to pass through, at whatever level it takes to equalize liquid flow and they can be re-set whenever needed, as further settlement occurs.
